

Fiber Optic Sensor Rotation Measurement Principle

Overview

A Fiber Optic Gyroscope is an optical instrument that uses the Sagnac effect to measure rotation. The Sagnac effect is a phenomenon where two light beams traveling in opposite directions in a rotating ring experience a phase difference proportional to the angular velocity of the ring. Radiation absorption creates electronic excited states that are trapped by localized defects for extended periods of. This paper provides an overview of basic approaches and a review of current state-of-the-art in fiber optic sensors for measurements of torsion, twist and/or rotation. Keywords: fiber optic sensors, twist sensors, rotation sensors, circular birefringence, linear birefringence, FBG, tilted FBG, long. The measurement of rotation is of considerable interest in a number of areas. For example, inertial navigation systems as used in aircraft and spacecraft depend critically on accurate inertial rotation sensors. A fiber optic sensor measures a physical quantity by modulating the intensity, spectrum, phase, or polarization of light traveling through the optical fiber system. In this article, we will explore the intricacies of FOGs, their working principle.
