

How to identify the positive and negative terminals of a fiber optic patch cord

Overview

Fiber optic patch cords do not have “polarity” in the sense of electrical positive and negative terminals, like a battery. Plugging them in “backwards” will not cause a short circuit, and it will not burn out or damage your equipment. Because fiber duplex links rely on matched transmit-receive alignment, polarity determines how cables, connectors. Two types of duplex fiber patch cords are defined in the TIA standard: A-to-A type shown in Figure 1 and A-to-B type shown in Figure 2. A link's transmit signal (Tx) must match its corresponding receiver (Rx) at the other end. Although it may seem obvious, fiber optic polarity is a frequent source of confusion and. Since most fiber optic links use two fibers transmitting in opposite directions to create a full duplex link, you need to ensure that transmitters are connected to receivers and vice versa. One of the most common faults when a newly-installed fiber network does not work is the fibers are not.
