Overview

Emission spectroscopy is an analytical technique used to identify and quantify elements by studying the light they emit after being energized. This method relies on the principle that atoms or molecules, when subjected to high energy, absorb that energy and subsequently release it as. Atomic emission spectroscopy (AES) is a method of chemical analysis that uses the intensity of light emitted from a flame, plasma, arc, or spark at a particular wavelength to determine the quantity of an element in a sample. It involves measuring the radiation emitted by atoms or molecules as they transition from higher energy states to lower energy states. Accuracy: The accuracy of an instrument is its capacity to give results that are free of. Optical emission spectrometry involves applying electrical energy in the form of spark generated between an electrode and a metal sample, whereby the vaporized atoms are brought to a high energy state within a so-called "discharge plasma". 1 shows a portion of the energy level diagram for sodium, which consists of a series of discrete lines at wavelengths that correspond to the difference in energy.

Atomic emission spectroscopy (AES) is a method of chemical analysis that uses the intensity of light emitted from a flame, plasma, arc, or spark at a particular wavelength to determine the quantity of an element in a sample. The wavelength of the atomic spectral line in the emission spectrum gives the identity of the element while the intensity of the emitted light is proportional to the number of atoms of the element. The sample may be
