

Principle of Signal Enhancement in Optical Splitters

Overview

Optical splitters can be categorized into two types: passive and active. Active splitters, on the other hand, are powered devices that use electronics to improve signal strength and. Fiber optic splitters are essential passive devices in modern optical communication systems, enabling the division of a single light signal into multiple outputs or combining multiple signals into one. They are devices that split an incident light beam into several light beams at certain splitting. There are three main working principles of the fiber splitter: 1. Signal Input: The fiber splitter receives the optical signal from the upstream network node and enters the splitter through the input fiber. This article aims to provide a comprehensive understanding of the working principle, various types, applications, and selection. An Optical Splitter, also known as a beam splitter, is a passive optical device that divides a single input optical signal into two or more output signals.

According to the principle, fiber optic splitters can be divided into Fused Biconical Taper (FBT) splitter and Planar Lightwave Circuit (PLC) splitters. The FBT splitter is one of the most common. FBT splitters are widely accepted and used in passive networks, especially for instances where the split configuration is smaller (1x2, 1x4, 2x2, etc.). The PLC is a more recent technology. PLC splitters offer a better solution for larger applications. Wav
